The Genesys HTA System is designed to reduce menstrual flow in women who suffer from menorrhagia and allow them the potential to return to the activities that they love.

INDICATIONS: The Genesys HTA System is a hysteroscopic thermal ablation device intended to ablate the endometrial lining of the uterus in premenopausal women with menorrhagia (excessive uterine bleeding) due to benign causes for which hysterectomy is complete.

CONTRAINDICATIONS: The Genesys HTA System is contraindicated for use in a patient: whom the physician determines is not a candidate for adequate diagnostic hysteroscopy, who has an inability to undergo diagnostic or therapeutic hysteroscopy, who is pregnant (non-cancerous) structures can occur almost anywhere in the uterus, Fibroids and polyps may contribute to heavy periods. Infection – Infections of the uterus and cervix may cause heavy bleeding. Bleeding Disorders – If bleeding disorders such as hemophilia or von Willebrand’s disease are present, bleeding complications may occur. Hormonal Imbalance – An imbalance of estrogen and progesterone–hormones that control the buildup and monthly shedding of the endometrium, the inner lining of the uterus—can lead to heavy periods. Uterine Fibroids & Polyps – These usually benign (non-cancerous) structures can occur almost anywhere in the uterus. Fibroids and polyps may contribute to heavy periods. Infection – Infections of the uterus and cervix may cause heavy bleeding. Uterine Cancer – A rare, but potential cause of menorrhagia. Infection – An infection of the uterus or cervix can cause heavy bleeding. Hormonal Imbalance – An imbalance of estrogen and progesterone can lead to heavy periods. Abnormal Uterine Bleeding – Abnormal bleeding can be caused by hormonal imbalances, pelvic inflammatory disease, endometrial polyps, or adenomyosis. Venous or Arterial Anomalies – These can cause heavy bleeding. Abruption Placenta – This can lead to heavy bleeding.

How common is menorrhagia?

It is estimated that menorrhagia affects 1 in every 5 women. It is a common but treatable condition. This brochure is designed to help inform you about what menorrhagia is, and some of your treatment options, but before you make any decisions talk with your doctor.

What causes menorrhagia?

There are several different causes of menorrhagia. The most common are:

• Hormonal Imbalance – An imbalance of estrogen and progesterone–hormones that control the buildup and monthly shedding of the endometrium, the inner lining of the uterus–can lead to heavy periods.
• Uterine Fibroids & Polyps – These usually benign (non-cancerous) structures can occur almost anywhere in the uterus. Fibroids and polyps may contribute to heavy periods.
• Infection – Infections of the uterus and cervix may cause heavy bleeding.
• Bleeding Disorders – If bleeding disorders such as hemophilia or von Willebrand’s disease are present, bleeding complications may occur.
• Hormonal Imbalance – An imbalance of estrogen and progesterone can lead to heavy periods. Abnormal Uterine Bleeding – Abnormal bleeding can be caused by hormonal imbalances, pelvic inflammatory disease, endometrial polyps, or adenomyosis. Venous or Arterial Anomalies – These can cause heavy bleeding. Abruption Placenta – This can lead to heavy bleeding.

What is excessive menstrual bleeding, or menorrhagia?

Excessive menstrual bleeding, clinically known as menorrhagia, pronounced men-or-ah-zha, is a prolonged or abnormally heavy menstrual period. The following symptoms may be indicative of menorrhagia:

• Periods lasting longer than seven days
• Soaking through one or more sanitary pads or tampons in an hour
• Menstrual flow that includes large blood clots
• Menstrual flow that is heavy enough to interfere with your daily activities

We understand how debilitating heavy periods can be. That is why we designed the Genesys HTA System to give you the potential opportunity to return to the things you love to do. The Genesys HTA System therapy is an outpatient procedure that uses heated saline to treat the uterine lining, or endometrium. Once treated, most women no longer experience the symptoms or effects of a heavy period. Many women stop having their period altogether.

As with any menorrhagia treatment, this may or may not be appropriate for you, so consult with your doctor to find out if the Genesys HTA System therapy is right for you.

Excessive menstrual bleeding, or menorrhagia?

Excessive menstrual bleeding, clinically known as menorrhagia, pronounced men-or-ah-zha, is a prolonged or abnormally heavy menstrual period. The following symptoms may be indicative of menorrhagia:

• Periods lasting longer than seven days
• Soaking through one or more sanitary pads or tampons in an hour
• Menstrual flow that includes large blood clots
• Menstrual flow that is heavy enough to interfere with your daily activities
• Fatigue or other anemia-like symptoms

If you are experiencing any of these symptoms, consult with your doctor about the possibility that you may have menorrhagia.

• Fatigue or other anemia-like symptoms

If you are experiencing any of these symptoms, consult with your doctor about the possibility that you may have menorrhagia.
How can menorrhagia be treated?

There are a variety of treatment options available to you. Some of these are listed below. To determine the right course of action and to make sure that you thoroughly understand all the benefits and risks, talk with your physician.

Drug Therapy

Hormones and NSAIDs are both commonly used drug therapies. Hormones are delivered through a variety of methods, most commonly birth control pills or an intrauterine device. However, these methods are not always effective at controlling excessive bleeding. Additionally, as common to hormonal treatments, some women may experience an increased risk of blood clots and breast cancer, or side effects such as high blood pressure, headaches or migraines, depression and weight fluctuation.5 Talk to your physician about other drug therapy options. Drug therapy may be a treatment for women who wish to have more children, as this treatment should not have an effect on fertility.

Dilation and Curettage

An outpatient procedure that scrapes away the endometrium and may provide temporary relief of heavy periods. This is generally not a long-term solution as relief usually lasts for only a few cycles. Risks include perforation of the uterus wall, injury to the bowel or other internal organs, bleeding and infection. This treatment may be an option for women who wish to have more children as the treatments should not have an effect on fertility.

Endometrial Ablation

Endometrial ablation is a procedure that is intended to treat and remove the lining of the uterus. The uterine lining or endometrium is tissue that thickens and sheds in cycles causing your period. After this tissue is removed, most women see a marked reduction in the heaviness of their menstrual flow, and some may never experience a period again. It may be performed on an outpatient or office setting. There are several ways in which endometrial ablation can be done: through heated fluid, a heat balloon, microwave energy, freezing, radiofrequency or electrosurgery. Not all patients will experience a satisfactory reduction in bleeding so all treatment options should be discussed with your physician. Risks for endometrial ablation procedures include infection, bleeding, injury to organs including perforation and/or burns. Although endometrial ablation significantly decreases the likelihood of pregnancy, it is not a sterilization procedure. You should seek advice from your physician if you wish to prevent pregnancy.

What is the Genesys HTA™ System? How does it work?

The Genesys HTA System treatment uses a sheath that is employed by your physician to perform an endometrial ablation. The system allows saline heated to 190ºF (99.4ºC) to be circulated in the uterus. After a slight dilation of the cervix, a slim procedure sheath will be placed in your uterus. Your uterus will be filled with room temperature saline. The saline will conform to your uterus, and circulate throughout the procedure (Figure 1). Your physician will then look inside your uterus with a hysteroscope, or a small camera, that fits inside of the procedure sheath. The saline circulating in your uterus will then be heated to 90ºC (194ºF) by the Genesys HTA System Console. As the heated saline comes in contact with the uterine walls, the saline will begin to heat the endometrium (Figure 2). This heat is intended to destroy the endometrium. This treatment cycle takes about 10 minutes. After the treatment cycle has been completed, the uterus will be flushed with cool saline (Figure 3). The cool saline is drained and the procedure sheath is removed.

Who is a candidate and is it the right treatment for me?

The Genesys HTA System is used in premenopausal women with menorrhagia (excessive periods) for whom childbirth is complete. Only you and your physician can decide if this is the right treatment for you. Your physician may want to do some preliminary tests to determine what is causing your menorrhagia such as a pap smear or an ultrasound.

What will I experience during the procedure?

You and your physician will decide what anesthesia will be best for you. Your options for anesthesia are to be fully asleep so that you do not feel anything during the procedure, to be partially sedated so that you feel light pain during the procedure, or to receive only local anesthetics and be fully awake during the procedure. If you choose to be awake, your physician may administer anesthesia such as mild cramping, during the procedure but it should not be painful. Your physician may give you pain medication before the procedure to help reduce cramping during or after the procedure.

What should I expect after my treatment?

You can expect some light cramping the day of your treatment. Some other common side effects you may experience include nausea and vomiting. Most women are able to return to normal activities by the next day. However, you should speak with your physician about resuming sexual activity. As your endometrium begins to slough off after the treatment, you may experience some discharge or other symptoms similar to your menstrual period. These symptoms may occur for several weeks after your treatment. You should not use tampons for seven days after your procedure to reduce your risk of infection. Your periods may continue to be heavy for a few months after the procedure as part of the healing process. However, this should improve after a few months. If you experience two days of heavy bleeding, abdominal or pelvic pain, a fever, or pain that increases over time beyond 24 hours after the procedure, call your physician immediately.

What can I expect from my Genesys HTA System treatment?

The majority of women see a dramatic decrease in the length and heaviness of their period. In clinical trials, after three years the majority of women reported a reduction of bleeding to normal levels or less. Many patients who completed the study, 98% of women were satisfied with their periods.

After the Genesys HTA System procedure can I get pregnant?

You should not have this procedure if you desire to get pregnant in the future. A significant decrease in endometrial ablation may decrease your chances for pregnancy, it does not prevent you from getting pregnant. A pregnancy after endometrial ablation would be high risk for both mother and child. Contraception or sterilization should be used after this treatment. If you wish to prevent pregnancy, it can still occur. Please discuss your birth control options with your physician.

What are the risks?

Your physician should explain all the potential risks of your menorrhagia treatment to you. Possible risks for all endometrial ablation procedures are: perforation (creation of a hole) of the uterus, bleeding, infection, injury to organs within the abdomen (e.g., bowel) and polyps or to adjacent tissue (e.g., cervix and vagina). post-ablation uterine stimulation syndrome (a complication in women who have undergone tubal sterilization following endometrial ablation that can occur as long as 10 years after your ablation), and delayed diagnosis of cancer of the endometrium.

The risk of serious injury such as perforation (creation of a hole) of the uterus and injury to internal organs with the Genesys HTA System is low. However, there is a risk that heated fluid may leak out of your uterus during the procedure and result in a burn to your vagina or surrounding areas. These burns are usually treatable by your doctor with medicated cream. In very rare cases, it may be necessary to seek specialized care from a burn center.

Glossary

Cervix – the lower part of the uterus that extends into the vagina.

Endometrium – the membrane that lines the uterus. The endometrium thickens and then sheds during menstruation.

Fallopian Tube – the thin duct that connects the ovaries to the uterus. The eggs released from the ovaries travel down these tubes and into the uterine cavity.

Menorrhagia – a prolonged or abnormally heavy menstrual period.

Ovaries – the glands in which eggs, or ovum, are produced and released monthly. These organs also produce estrogen and progesterone.

Uterus – The female reproductive organ. It is a muscular cavity in which a fetus develops during gestation. Sometimes referred to as the womb.

Vagina – a tunnel through which blood and tissue is passed during menstruation and through which a baby passes during birth.

Figure 1: Uterus being filled with saline.

Figure 2: Uterus with circulating heated saline and subsequent blanching of uterine lining.

Figure 3: Post-procedure, uterus being cooled with room temperature saline.
