Selection criteria for intrarenal pressure sensing ureteroscopes

Risk factors for postoperative infection after ureteroscopy

With recent advancements in technology, ureteroscopy (URS) has become the primary surgical treatment modality for upper tract kidney stones.\(^1,2\)

Recent studies have demonstrated that the risk of infection and even sepsis after URS may be significant. Our recent meta-analysis and systematic review found a 5.0% pooled incidence of postoperative urosepsis (95% CI, 2.4-8.2)\(^3\) and our recent large retrospective study (n=104,100) of commercially insured U.S. patients reported a 5.5% rate of sepsis post-URS.\(^4\) This risk may seem low. However, considering there is a 10.1% prevalence rate of kidney stone disease in the U.S. (based on 2013-2014 data)\(^5\) and the impact on healthcare utilization and cost,\(^4\) it becomes a significant outcome that requires considerable consideration.

Our systematic review and meta-analysis identified the following risk factors associated with increased postoperative urosepsis risk:\(^3\)

- Preoperative ureteral stent (OR=3.94; 95% CI, 2.36-6.60)
- Preoperative positive urine culture (OR=3.56; 95% CI, 2.11-6.01)
- Comorbidities: ischemic heart disease (OR=2.49; 95% CI, 1.38-4.48), diabetes (OR=2.04; 95% CI, 1.04-4.03)
- Longer procedure time (mean difference=9 min; 95% CI, 2-16, p=0.02)
- Older age (mean difference=2.7 years; 95% CI, 1.0-4.4, p=0.002)

Our retrospective study identified the following risk factors for sepsis post-URS, in addition to many of those identified in our meta-analysis:\(^4\)

- History of sepsis in 6 months prior to index URS (OR=3.51; 95% CI, 3.08-3.99)
- Hospitalization in 6 months prior to index URS (OR=1.17; 95% CI, 1.06-1.29)

Additionally, in a 2020 systematic review, the following were associated with infectious complications after URS:\(^6\)

- Neurogenic bladder
- Female gender

Finally, struvite stones are embedded with gram-negative bacteria, which can produce endotoxin.\(^7\) A retrospective study showed an association between struvite stones and systemic inflammatory response syndrome (SIRS) (OR=3.331; 95% CI, 0.971-11.426).\(^8\) SIRS is a serious condition closely associated with sepsis.\(^9\)
Risk factors for postoperative infection after URS (cont.)

A number of studies have demonstrated that irrigation-related factors are associated with postoperative infection and SIRS.\textsuperscript{8,10,11} One of these studies was a randomized single-blind clinical trial comparing pressure irrigation at 80 mmHg vs. 200 mmHg during percutaneous nephrolithotomy (PCNL).\textsuperscript{11} It was determined that the higher-pressure irrigation was an independent predictor of SIRS postoperatively. Increased irrigation pressure has been shown to result in increased intrarenal pressure.\textsuperscript{12}

Other than the type of irrigation (pressure vs. non-pressurized) being used, additional factors can impact intrarenal pressure. Specifically for sepsis and intrarenal pressure, one factor to consider is the use of a ureteral access sheath (UAS). While there are risks associated with using a UAS, research suggests that the use of a UAS can reduce the risk of postoperative sepsis\textsuperscript{13} (although this hasn’t been found in all studies).\textsuperscript{14} It is theorized that this is most likely due to the reduction in intrarenal pressure associated with the use of a UAS.\textsuperscript{15,16}

Significant evolution in flexible ureteroscope technology

Since the introduction of the flexible ureteroscope, advancements continue to make them smaller, more maneuverable, and with better image resolution. The flexible ureteroscope has revolutionized the way we treat kidney stones.\textsuperscript{17} The launch of the first single-use ureteroscope in 2016 established a new paradigm in the surgical management of kidney stone disease in terms of access, indication, and financial costs for both the healthcare ecosystem and surgeons.\textsuperscript{18} Boston Scientific pioneered this movement with the introduction of the LithoVue™ Single-Use Digital Flexible Ureteroscope. Since then, new innovations in chip technology, camera image quality, and maneuverability have brought about a new generation of single-use ureteroscopes across the globe.

The LithoVue™ Elite Single-Use Digital Flexible Ureteroscope, the latest innovation from Boston Scientific, builds on the LithoVue™ Single-Use Digital Flexible Ureteroscope and is the first and only ureteroscope with real-time pressure monitoring. Additionally, the LithoVue Elite Ureteroscope improves upon essential functionalities such as camera image quality.
Selective approach

Similar to the criteria developed for single-use ureteroscopes in specific cases (i.e., large lower pole stone burden), facilities may benefit from using a clinical decision pathway tool to help decide when to use a pressure sensing ureteroscope.

Consider using the LithoVue Elite Ureteroscope in patients at risk of postoperative infectious complications, including sepsis, using the following selection pathway to potentially maximize the benefits at your institution:

**Will the case require a flexible ureteroscope?**

- **NO** Prepare alternative equipment as necessary.

  **YES**

  **Are any of the following criteria applicable to this case?**
  
  1. Preoperative ureteral stent
  2. Preoperative positive urine culture
  3. History of sepsis prior to URS (within 6 months)
  4. Known struvite stone former

  **YES** Consider using a pressure sensing ureteroscope to monitor intrarenal pressure and keep it as low as possible while maintaining good visibility.

  **NO**

  **Are any 2 of the following criteria applicable to this case?**
  
  1. History of diabetes
  2. History of ischemic heart disease
  3. Older age
  4. Recent hospitalization (within 6 months)
  5. Long procedure time is anticipated
  6. Female gender
  7. Neurogenic bladder

  **YES** Consider using a pressure sensing ureteroscope to monitor intrarenal pressure and keep it as low as possible while maintaining good visibility.

  **NO**

*These factors have been associated with high risk (>3.0 odds ratio indicated in literature) of postoperative infectious complications following URS.*
